Social intelligence or “emotional intelligence” was a term that became popularized in the mid-1900s. Today, the concept is still a source of discussion, and researching it on any search engine will yield a wide array of results. Some articles discuss the importance of social intelligence in various industries, while others provide readers with the necessary steps to improve their own SI. Though many scholars study SI and have done extensive research on its importance in different fields, in reality, there is very little scientific data that can be used to support the claim that social intelligence differs from general intelligence, or even exists. Even through inspecting our day to day interactions with other people it is clear to see that everyone presents varying levels of social capabilities and “emotional intelligence.” This research is an attempt to extend and improve upon a previous test run by Joshua Hartshorne and Steven Pinker. The test will include a mixture of linguistic and nonlinguistic tasks in order to prove, or disprove, the existence of SI by measuring its potential indicators.
